Understanding the Antifouling Coating Options Available to Ship Owners

All products supplied and technical advice or recommendations given are subject to our standard Conditions of Sale.
Agenda

- Background
  - Why do we need antifoulings?
  - Measuring the effectiveness of coatings
  - Fouling organisms and controlling factors
  - Antifouling technology options
Why do we need antifoulings?

- “Minimise fuel costs”
- “Maximum speed”
- “Less engine wear”

- “Maximum cargo days”
- “Lower stack emissions”
- “Minimum M&R costs”

- “High speed”
- “Readiness for war”
- “Noise minimisation”

- “Getting there on time”
- “Minimise fuel costs”
- “Safe for the environment”

All products supplied and technical advice or recommendations given are subject to our standard Conditions of Sale.
Why do we need antifoulings?

NEEDS = NEED TO AVOID

Meet schedules
Minimise bunker costs
Minimise SOx & NOx
Minimise repair cost (engines)
Vessel appearance

Drag

Maximum operating Efficiency
Minimum fuel consumption
Why do we need Antifoulings?

- The control of surface roughness and of fouling is essential to keep hulls as smooth as possible, and thus minimise drag
- Our primary aim is to provide “smooth hulls”
- Prevent the translocation of invasive species
What is Fouling?

- Fouling is the settlement of aquatic organisms onto an immersed substrate

- Antifouling technology aims to protect the immersed substrate from fouling: i.e. deter fouling settlement, maintain a foul-free ‘clean’ surface
The Fouling Problem

Fouling Organism
- Slime
  - Red
- Weed
  - Brown
  - Green
- Animal
  - Soft-bodied
    - Hydroids
  - Hard Bodied
    - Barnacles
      - Tube worms
      - Mussels
    - Sponges
The Fouling Problem – Factors Affecting Fouling

- Temperature
- Speed/Motion
- Light & Nutrients
- Other Factors: Water salinity and pollution

- Generally speaking: greatest risk of fouling is with low activity trading extensively in tropical or sub tropical coastal environments:
- Faster deep-sea vessels at highest risk of fouling when in port (often tropical/sub tropical) for loading/unloading
Fouling

All products supplied and technical advice or recommendations given are subject to our standard Conditions of Sale.
Why Use Antifouling Coatings?

Fouling increases the hydrodynamic drag of a vessel therefore more energy is required to drive through water

- USN field studies: fuel consumption increases by ~40% due to severe fouling
- 250,000 dwt super tanker: Annual fuel bill ~ $1.8 million. If totally fouled, fuel bill will increase by $720,000
- Consider entire world fleet ~90,000 vessels
The Effects of Fouling

Slime ~ 8% drag increase

Weed ~ 10% drag increase

Hard ~ 40% drag increase

All products supplied and technical advice or recommendations given are subject to our standard Conditions of Sale.
What drives the AF market?

- **Drivers**
  - Main driver for antifoulings is legislation
    - Biocide registration
    - Solvent emissions
    - Substance registration
  - **Other drivers**
    - Product Stewardship
    - Raw material costs
    - Petroleum derivatives costs

All products supplied and technical advice or recommendations given are subject to our standard Conditions of Sale.
• There are three main biocidal antifouling technologies currently available:

• **Self-polishing copolymer (SPC)**
• **Self polishing antifouling**
• **Controlled depletion polymer (CDP)**

• These technologies have:
  • Differing effects on roughness
  • Differing abilities to resist fouling
There are three main soluble acid binder options to enable biocide release in sea water:

- SPC
- Self polishing antifouling
- CDP
Antifouling Technology

• When using biocides to control fouling there are two key issues:

• Biocides – types, quantities

• Release mechanism – binder technology
Antifouling Technology

- For biocides to be effective, they have to be released into the sea from the antifouling.

- Sea water is alkaline (pH ~ 8) and biocidal antifoulings work by having an acidic binder component that can dissolve in sea water, thus releasing biocides.
Water migrates into the paint film

Dissolved rosin and biocides migrate into the sea

Insolubles left in the leached layer

Dissolution continues, leached layer grows

Dissolution stops when leached layer is too thick to allow water to penetrate

All products supplied and technical advice or recommendations given are subject to our standard Conditions of Sale.
• There is a slow dissolution of the paint film in sea water, similar to the way a bar of soap disintegrates when left in water

• This dissolution gradually slows down over time, due to the formation of insoluble materials at the surface

• The maximum effective life is typically 36 months on the underwater sides, but it can be up to 60 months on the flat bottom of the ship

• Leached layers can become thick, increasing roughness, and care is needed to remove as much as possible before overcoating at M&R drydocking
• Rosin has some disadvantages:
  – it is a brittle material, and can cause cracking and detachment
  – it reacts with oxygen and has to be immersed relatively quickly
  – It does not prevent water going into the antifouling paint film

The effect of fouling on a CDP ship

Start of weed fouling on CDP

% Increase in Fuel Consumption

months

0 10 20 30 40 50 60

-2 0 2 4 6 8

CDP  SPC
• The words used to describe CDPs can be very confusing:
• Key tests for CDP a/f paints are:
  – Use of rosin, or rosin derivatives (ASTM D-1542)
  – Higher solids (55~60% vol. solids)
  – Thick leached layers
  – Film integrity is generally poor, and re-blasting is needed after 10 years
Summary:

- CDP (rosin-based) antifoulings are not as effective as Self Polishing Copolymer (SPC) systems.
- CDP products generally have thick leached layers, which limit performance and negatively affect re-coatability.
- However, CDP products have a place as the lowest cost per m², “value for money” antifoulings, and are suitable for use in low fouling areas or for vessels with short drydock intervals.
Antifouling Technology

Antifouling Technology

- SPC
- Self polishing antifouling
- CDP

*Interspeed 640 (US)
- Self-polishing copolymers (SPC) undergo a reaction ("hydrolysis") with sea water, to form an acid polymer which is then soluble in sea water.
- This results in thinner leached layers and thus much better control of biocide release.
- Reconsider the simple mechanism as before:
- Add in the SPC step:
• To date, only three SPC technologies have been commercialised:
  
  • Copper acrylate  
    (Polymer --- COO --- Cu --- R)
  
  • Zinc acrylate  
    (Polymer --- COO --- Zn --- R)
  
  • Silyl acrylate  
    (Polymer --- COO --- Si --- R₃)
SPC features

- Controlled, chemical dissolution of the paint film, capable of giving long drydock intervals (up to 60 months) and smoothing

- Predictable polishing, enabling “tailor-made” specifications by vessel type/operation

- Thin leached layers, so simple cleaning and re-coating at M&R

- Ideal for newbuildings:
  - Excellent weatherability
  - Fouling control during fitting out
  - Good mechanical properties (eg resistance to block squeeze etc)

All products supplied and technical advice or recommendations given are subject to our standard Conditions of Sale.
Water migrates into the paint film

Surface reacts with seawater ions and becomes soluble

Surface dissolves, releasing biocides.
Thickness lost

Coating stops working when only small leached layer remains

Reaction/solution continues, film gets thinner through polishing

All products supplied and technical advice or recommendations given are subject to our standard Conditions of Sale.

Marine Coatings

**SPC**
- Good film properties
- Polishing control
- Thin leached layer
- Control of biocide release
- Best AF performance

**CDP (rosin)**
- High volume solids content
- Polishing control
- Surface tolerant
- Good film properties
- Control of biocide release
- Good AF performance

International Paint
Patent: WO 00/43460
(27th July 2000)
• **Self polishing antifouling** technology works by a mixture of hydrolysis and hydration mechanisms combining SPC acrylic polymers with a certain amount of rosin.

• **Performance and price** are mid-way between the CDP (rosin-based) and SPC (acrylic) products.

• **3 years maximum on the vertical sides**, but 5 years on the flats, where fouling is less severe.

• Self Polishing antifoulings will give significant performance improvement over CDP Antifoulings for virtually all the major trading routes worldwide

• Self Polishing antifoulings are particularly suitable for vessels trading permanently in tropical and semi-tropical waters

• Self Polishing antifoulings have a thinner leached layer than CDP antifoulings, and have better film properties, so making M&R easier
“Brothers” 27,563 dwt bulker, April 2004, 31 mo.
Summary

- Self Polishing Antifoulings will deliver antifouling performance intermediate between CDP and Self Polishing Copolymer (SPC) products
All products supplied and technical advice or recommendations given are subject to our standard Conditions of Sale.
Biocide Free Antifoulings

- From an environmental perspective, most desirable approach to fouling control is one which does not rely on biocide release to achieve its effect
- Plethora of ideas proposed over the years
- Numerous patents issued
- Only foul release or low adherence systems have been commercialized successfully to date
Biocide Free Antifoulings
Technology – Present

- Silicone
- Silicone epoxy
- Siloxane
- Polysiloxane epoxy
- Fluorinated polysiloxane
- Epoxy
- Polyurethane
- Fluorinated polyurethane
- Wax
Low Adherence

- Concept of Low Adherence first considered in 19th century
- Discovery of fouling control properties of silicones was advent of commercial systems
- Another chemistry to be considered to great extent has been fluorinated polymers
Foul Release Coatings

- Foul Release is name given to technology which does not use biocides to control fouling
- Relies on 'non-stick' principle to minimize fouling adhesion to surface
- Most currently available are based on silicone technology
Foul Release Coatings - Silicone

• Low surface energy is one key characteristic
• Extremely flexible backbone allowing polymer chain to readily adopt lowest surface energy configuration
• Other important characteristics are coating thickness, elastic modulus and smoothness
• Fouling species prefer to settle on rough surfaces
